

# Some Observations on CGNs

Geoff Huston

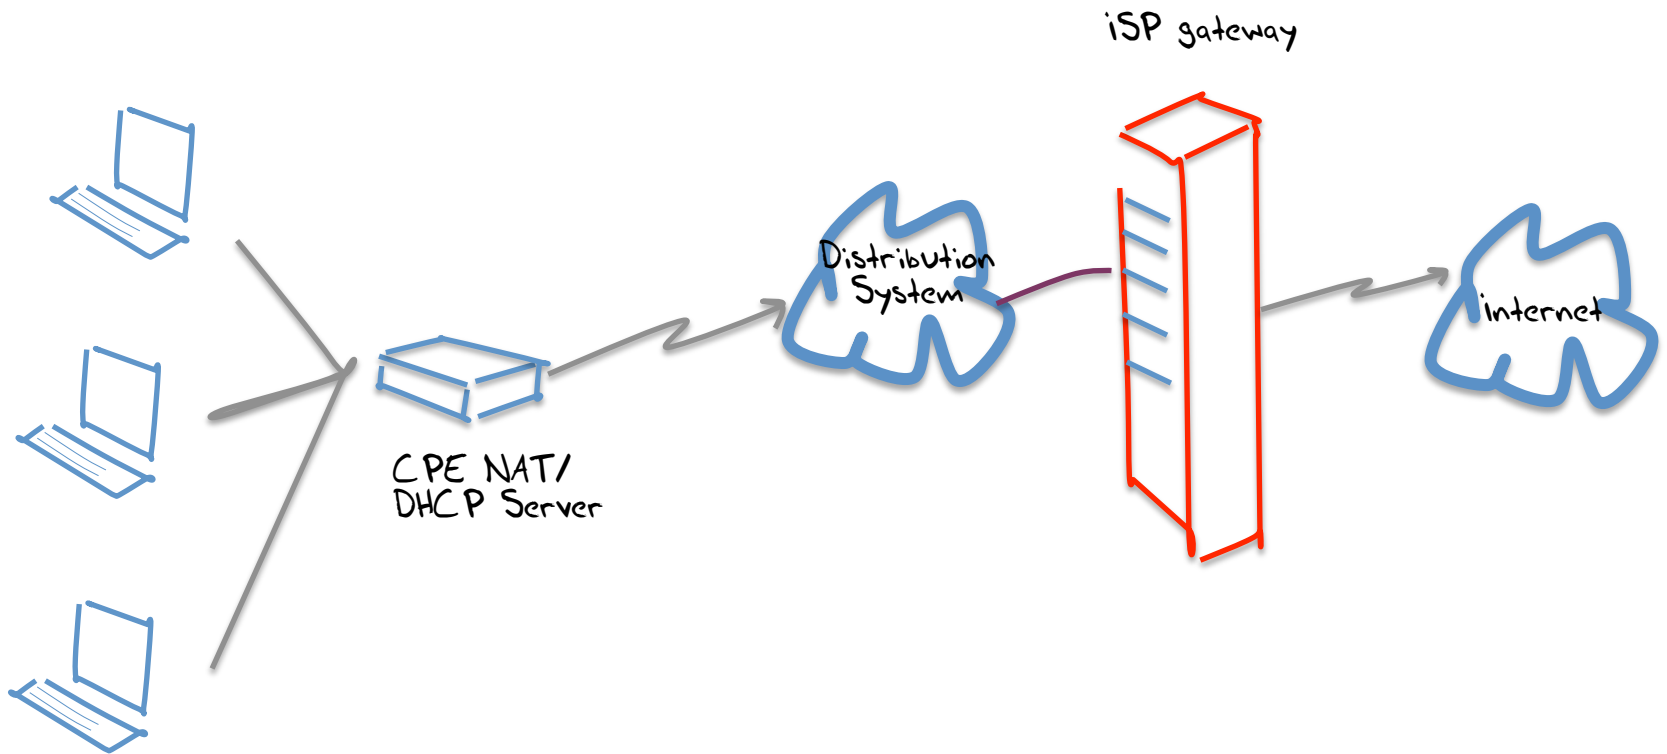

Chief Scientist

APNIC

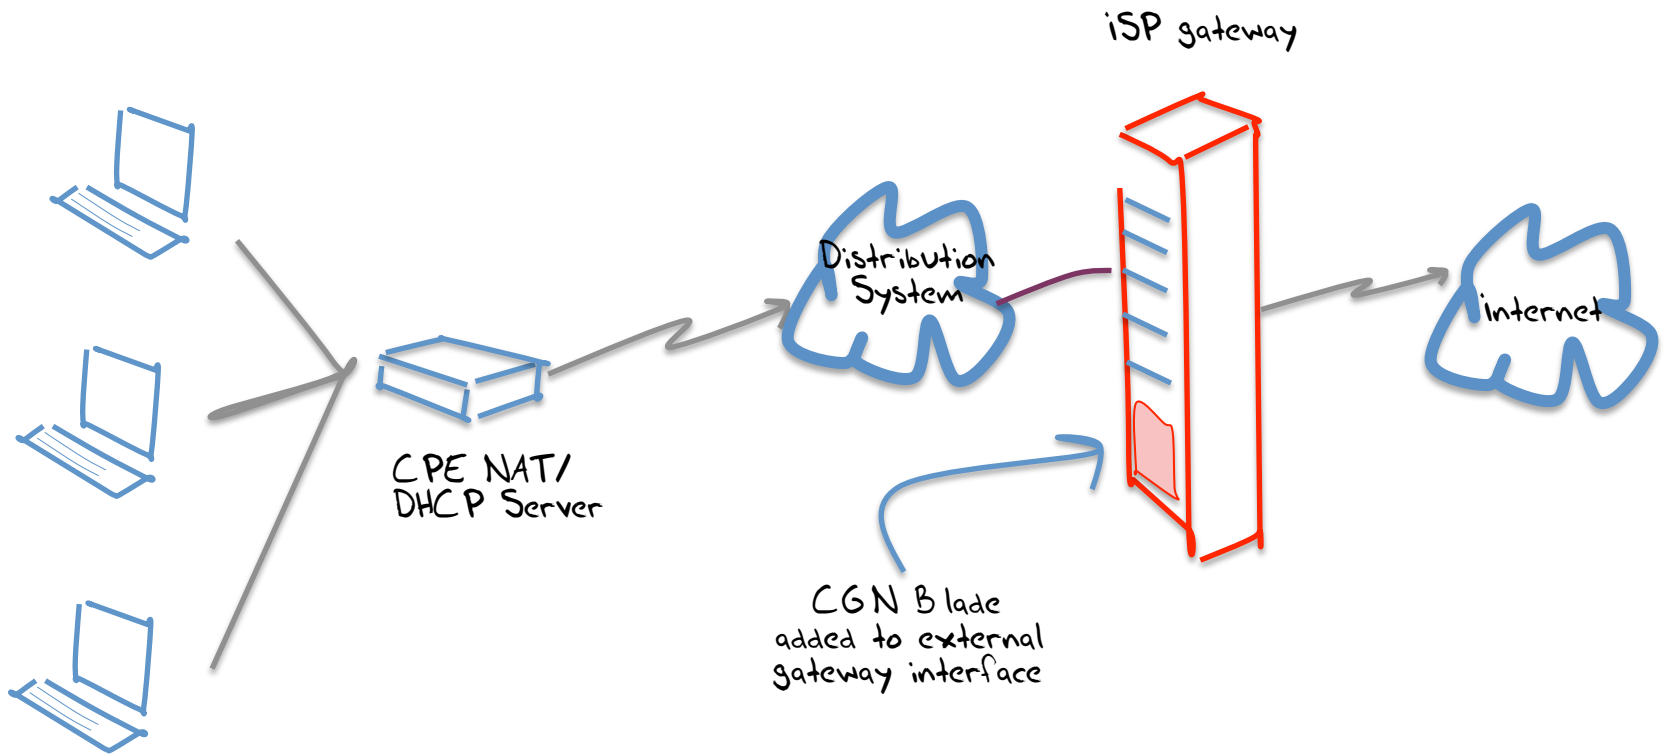

# The story so far..

- The status of the transition to IPv6 is not going according to the original plan:
  - Over the past three years APNIC (Asia Pacific) and the RIPE NCC (Europe and the Middle East) have exhausted their supplies of general use of IPv4 Addresses
  - ARIN have some 12 months to go, but this assumes a very constrained availability over this period
  - We we meant to have IPv6 fully deployed by now. This has not happened.
- What we are seeing is the increasing use of Carrier Grade NATs as a means of extending the useable life of the IPv4 Internet while we are still waiting for IPv6 to be viable in its own right

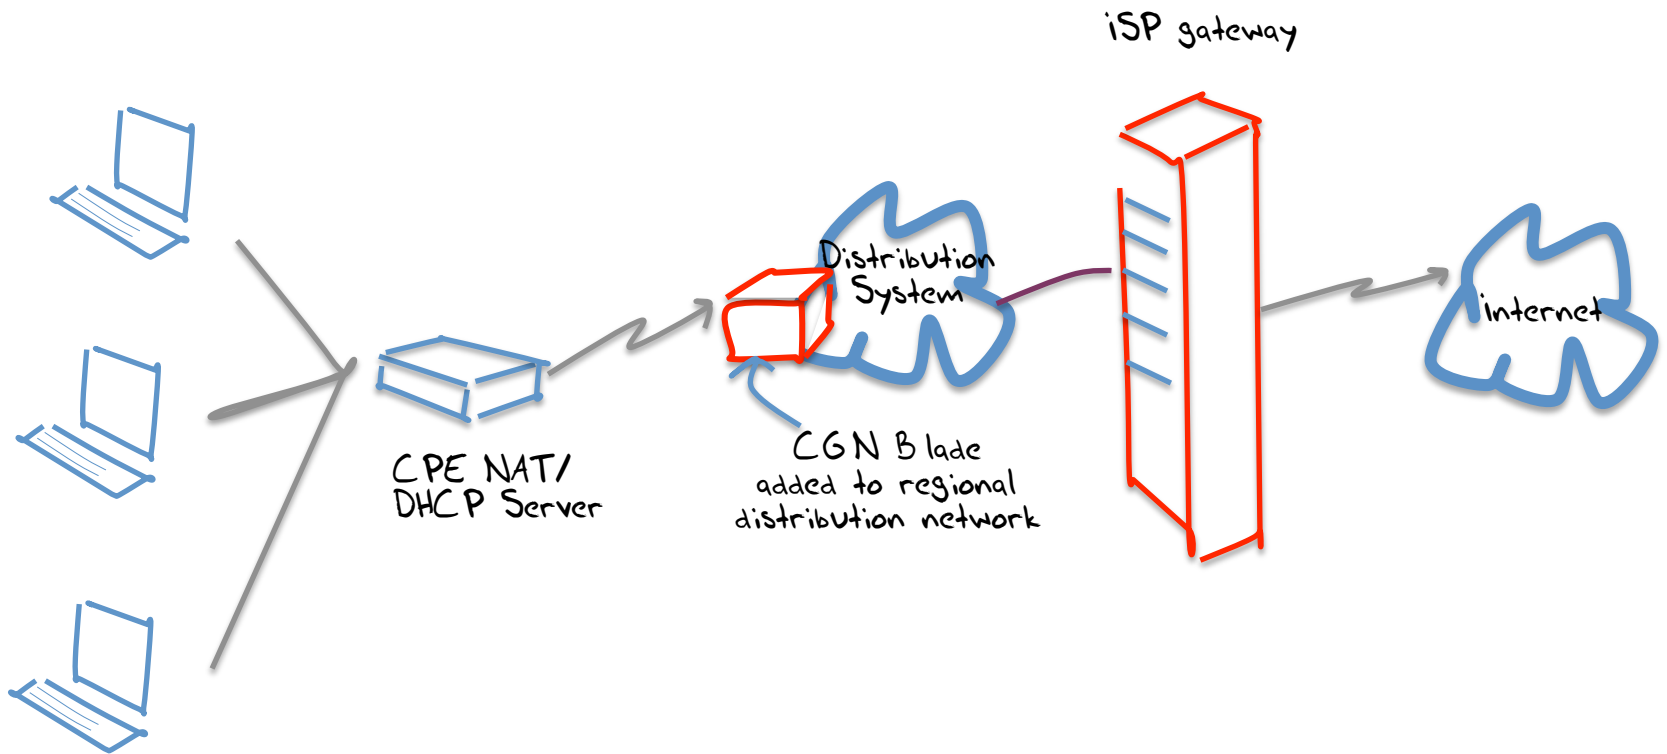

# Anatomy of an access network

# Anatomy of an access network

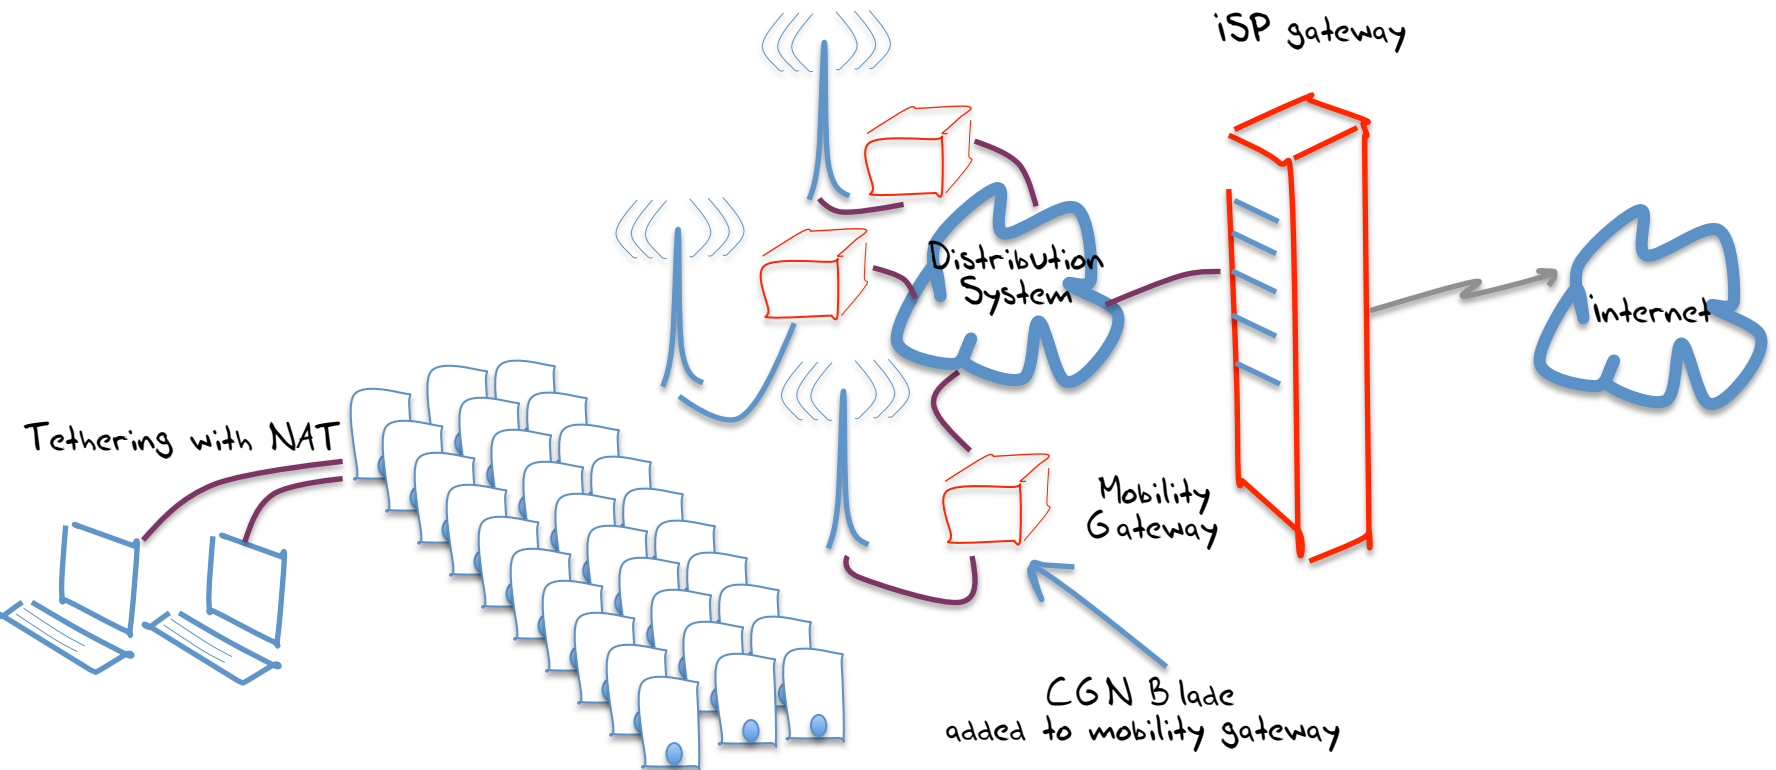

# Anatomy of an access network

# Anatomy of a <sup>mobile</sup> access network

# Anatomy of a <sup>mobile</sup> access network

in many cases the mobile network has used some form of CGN since its inception - its not a retrofit

No matter how its engineered, the result is much the same...

Yes, that's my phone using net 10!

# Variants of NAT44 CGN Technologies

Variant:	Address Compression Ratio
CGN with per user port blocks	10:1
CGN with per user port blocks + pooled overflow	100:1
CGN with pooled ports	1,000:1
CGN with <u>5-tuple binding maps</u>	>>10,000:1

The same public address and port is used simultaneously by multiple different internal users

# Adding IPv6 to the CGN Mix

- The space is not exclusively an IPv4 space.
- While CGNs using all-IPv4 technologies are common today, we are also looking at how to use CGN variants a mix of IPv6 and IPv4

*For example: Dual-Stack Light connects IPv4 end users to the IPv4 Internet across an IPv6 ISP infrastructure.*

- We can expect to see many more variants of ISP's address transform middleware when you are allowed to add IPv6 into the mix

## Example: 464XLAT

### What is 464XLAT ? (3)

#### • Network architecture

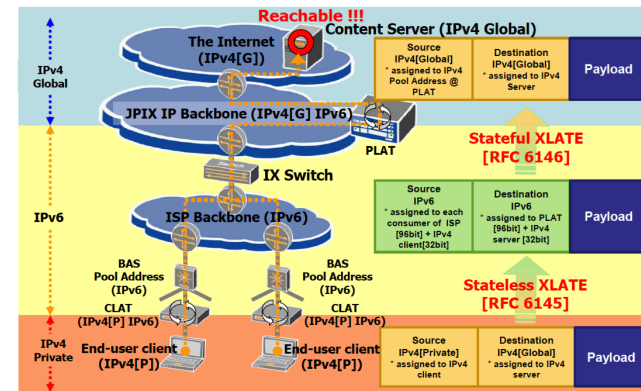

- This architecture consists of CLAT and PLAT have the applicability to wireline network (e.g. FTTH) and wireless network (e.g. 3GPP).

# So What?

## What still works with NATs:

- TCP should mostly work
  - The NAT binding is triggered from the initial outbound SYN exchange
  - The NAT binding is destroyed on FIN handshake, or idle timeout
- UDP should sort of work
  - The NAT binding is triggered on an outbound packet
  - The NAT binding is destroyed on idle timeout

# So What?

What may *not* work with NATs:

- TCP:
  - Long held idle TCP sessions
  - Long held TCP sessions
  - High intensity parallel TCP sessions (port exhaustion)
  - TCP fragments (IPv4)
  - Externally initiated sessions
- UDP
  - Idle UDP “sessions” (with varying degrees of “idle”)
  - UDP trailing fragments (IPv4)
  - Port agility in UDP
  - Externally initiated packets

# So What?

## What else won't work?

- Any transport protocol other than UDP or TCP
- Any form of failover and resilience in the light of component failure
- Theoretically, IPv6 is not intended to work with NATs (NAT66)
  - And in any case, there are issues with port-translating NATs and IPv6 Path MTU behaviours.
  - And some potential issues with multi-addressing and ULAs and NAT66 functions

# Where is this heading?

- IPv4 use is not stopping any time soon
- And the network is still growing
- We will need to drive the network a lot further down the road using CGNs in IPv4
- That implies an ever-richer set of network middleware in the network
- That raises some very fundamental questions for me about where this leads...

# How can we avoid:

- Escalating network costs
- Inflexible networks that support cached port 80 and limited port 443, and nothing else
- Port rationing
- A new round of application complexity to scavenge and retain NAT bindings
- End-to-end security as a premium charged option
- The demise of further basic innovation in communications
- User capture by the carriage provider
- A return to the dismal economics of vertically integrated carrier monopolies?
